5.1.2.2 Color conversion codes. The color conversion table maps the colors from one color/grayscale table into another color/grayscale table. If a user is unable, or does not choose, to use the primary color/grayscale table in an RPF file, the color conversion table can be used to map the primary colors into the closest matching colors within the alternate table. These names used to describe the <color/grayscale table id>s begin with the letters CCT/. The number immediately after the slash (/) is the <color/grayscale table id> of the primary color table, and the number after the arrow (->) is the alternate color table id. In cases where the primary and alternate color tables contain the same color planes, the numbers after the slashes will be the same. In these cases, the color converter table is often used to map a larger number of colors in the primary color table to a smaller number of colors in the alternate color table.

a. In an example use of a color conversion table, assume that an RPF file has two <color/grayscale tables id>s and one <color converter table id>. The two [color/grayscale table] are RGBM (<color/grayscale table id> = 2) and therefore the appropriate [color converter table] would map the primary RGBM into the alternate RGBM, (<color converter table id> = 5). The color conversion table is a mapping of the colors from the primary RGBM color table to the alternate RGBM color table as in figure 1. A call to display color X from the primary color table is routed to the color conversion table, where the index of X is mapped to the index of Y, a color in the alternate color table.

5.1.3 Zone codes for ARCD data. Zone codes are used in conjunction with the data series codes (5.1.4) to construct the <data series and zone> codes in 5.1.5. For products where zone code and/or data series is not applicable, the <data series and zone codes> shall consist of a 3-byte descriptor applicable to a particular product. No <data series and zone codes> are currently registered for such products.

5.1.3.1 Zone codes for DTED data. Zone codes are used in conjunction with the data series codes (5.1.4) to construct the <data series and zone> codes in 5.1.5. The zone codes for RPF data that is zoned similar to DTED data have the following zone codes.

Zone Number	Equatorward Latitude	Poleward Latitude
1,6	0°	50°
2,7	50°	70°
3,8	70°	75°
4,9	75°	80°

5.1.4 Data series codes. The data series codes are used in conjunction with the zone codes (5.1.3) to construct the <data series and zone> Codes in 5.1.5. The specific methodology for creating the data series and zone codes is described in MIL-STD-2411.

5.1.5 Data series and zone codes. The <data series and zone> codes are three digit alphanumeric codes derived from the two digit Data Series Code (see 5.1.4) and the one digit Zone Code (see 5.1.3). The following are *examples* of valid codes currently defined for RPF data. Other valid <data series and zone> codes (for city graphics, etc.) can be created by combining data series codes with the ARC zone codes in the same fashion.
